How to Remote Debug on Windows-CE devices
with Microsoft Visual Studio

1. Introduction

This manual contains the information you need to remote debug on Windows-CE devices based target device.

Advantech provides library and sample code which allows developers and end users to connect I/O modules, perform configurations, and simple testing of the I/O.

This manual also supplies information about how to apply Advantech DiaignAnywhere software to remote control Advantech controllers, including accessing remote desktop and file transfer.

1.1. Organization of This Manual

This user manual is divided into the following sections:

- Introduction
- Setup environment
- Start Debugging
- Troubleshooting

Introduction

This section gives the user a basic idea of this manual.

Setup environment

This section describes how to set up remote debug environment.

Start Debugging

This section gives the user step-by-step procedures of remote debugging.

Troubleshooting

This section provides troubleshooting information and procedures for remote debugging.
2. Setup environment

This section describes how to set up your remote debug environment on host PC and the target device.

2.1. Target Device

You need to copy the CoreCon files to target device. On the development computer, these files are automatically installed when you install Microsoft Visual Studio. They typically install to

\[ C:\Program Files\Common Files\Microsoft Shared\CoreCon\1.0\Target\wce400\<Hardware Platform> \]

For APAX-5520/5620, which is based on the ARM hardware platform, these files are in \[ C:\Program Files\Common Files\Microsoft Shared\CoreCon\1.0\Target\Wce400\armv4i \]; For APAX-6572 ADAM-5560, copy files in \[ x86 \] directory.

The CoreCon files to copy to target device are:

- Clientshutdown.exe
- Cmaccept.exe
- ConmanClient2.exe
- DeviceDMA.dll
- eDbgTL.dll
- TcpConnectionA.dll

Now, we apply Advantech **DiagAnywhere** to transfer the above files to the target device. For example, we create a folder named “WinCEDebug” under “Harddisk” on target device, and then copy CoreCon files to the folder.
2.2. **Host PC**

You have to configure Microsoft Visual Studio for debugging.

In Visual Studio, go to the **Tools** menu and click **Options**.
You will then be prompted for the options dialog box. Expand **Device Tools** and click **Devices**. Under Show devices for platform, select **Windows CE**. Set **Windows CE Device** as default device. Select **Windows CE Device** in Devices list and press **Properties** to set connection configuration.

Set default output location as **Program Files Folder**. Under Transport, select **TCP Connect Transport** and click **Configure**.
You will then be prompted for the TCP/IP transport window. Select **Use specific IP address**, and enter the target device’s IP address. Click **OK** as needed to exit the dialog box.
3. Start Debugging

Now that you have set up Visual Studio to connect to target device, you need to prepare target device to connect to Visual Studio.

3.1. Connect to Visual Studio

You can connect to target device by using Advantech DiagAnywhere.

Click “Start->Programs->Command Prompt” and open a command prompt.

Navigate to the directory to which we copied the connectivity files.

For more detailed information about directory path, see Chapter 2.1.

At the command prompt, type `conmanclient2`.

Open another command prompt, type: `cmaccept`.

Note!

Quickly move to the next step because you have only three minutes to initiate a connection between your development computer and your device.
3.2. Start to Debug

Now, you can deploy your application for debugging.

Open the program you want to debug and set break points.

In the Visual Studio, on the **Debug** menu, click **Start Debugging**.

You will then be prompted for the dialog box. Select **Windows CE Device** and click **Deploy**. Visual Studio will connect to your device and download your application onto it.
**Note!**

On target device, the system will create the program folder under *Program Files* and copy your application automaticity while starting to debug. If you encounter the problem below, it means that your program calls functions in DLL file. You have to copy your DLL file from host PC to target device.

You can apply *Advantech DiagAnywhere* to transfer DLL files to program folder on target device. The program folder can be found under *Program Files*. 
After the program has been successfully deployed, you will see the program was stopped at break point.

On target device, you will see the program halts. You can resume the program by issuing another debugging command, such as continue, step, or next.
Now, it is your turn to debug all your stuff.
4. Troubleshooting

4.1 ActiveSync bootstrap initialization failed

In host PC, execute the command **`del /s "%USERPROFILE%\Local Settings\Application Data\Microsoft\Corecon\*.*`** under command prompt.
On target device, you have to connect to visual studio again. For more detailed information about how to reconnect, see Chapter 3.1.

4.2 Mapping path failed
If you encounter this problem, check the following information on target device:

- Check whether the program fold exists under Program files. For more detailed information, see Chapter 2.2.
- Check whether the dynamic link library (.dll) exists in the specified folder. For more detailed information, see Chapter 3.2.

4.3 commandClient2 execute abnormal
On the target device, close command prompt and execute commandClient2 again.
